

# Automated Service Builder

## Framework for Globally Distributable processing

### Overview

ASB is a platform and application agnostic solution for implementing complex processing chains over globally distributed processing and data resources. ASB provides a “low coding” solution to develop a data processing facility based on orchestrated workflows.

Users can define, configure and run algorithms embedded in workflows. ASB provides functions to register new processes, import and dockerize user defined algorithms, graphically edit workflow definitions, executing processors with user-defined parameters, and access the results either through a product catalogue or an FTP server. ASB has implemented a customisable ontology-based mechanism that verifies the consistency of the dataflow between processes. Only compatible process parameters may be connected to pass data within workflows. Unconnected input parameters are treated as user defined inputs for which a Web-based interactive interface is automatically generated.

ASB’s Generic Flexible Orchestration means that processor tasks are orchestrated by the workflow engine independent of the location of the actual executable files and independent of the

underlying programming languages and related technologies.

User algorithms are packaged, deployed and executed on user-selected platforms which can be where the data is located.

Algorithm developers and software specialists benefit from ASB’s Process Import Tool that ingests user’s own algorithms and libraries to be included in the ASB knowledge base (Figure 1). Imported algorithms can be used by other users providing a platform to co-develop algorithms for faster development cycles, easy substitution of modules in processing chains for comparative studies and scalability at processing platform and algorithm levels.

ASB is offered as a service, implemented by Space Applications Services or as a product to develop a processing facility supported by Space Applications Services.

### Using ASB

ASB is a “low coding” solution that provides tools to allow users to ingest algorithms and libraries into ASB. ASB caters for users with preliminary algorithms to test or algorithms ready to be used to create a systematic highly scalable big data processing service. In both cases the approach to ingesting the user’s algorithms is the same. With algorithms coded and libraries identified to be used ASB provides an import tool to ingest the algorithms to build process images and populate the Knowledge Base. The Process Import Tool is implemented as a separate module that can be packaged and run either separately, or within a Docker container.

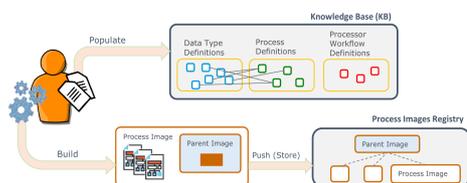

Figure 1 Process to populate the ASB framework

### APPLICATIONS

ASB caters for users with preliminary algorithms to test or algorithms ready to be used to create a systematic highly scalable big data processing service.

ASB is designed for defining, managing and executing complex heterogeneous processing chains (workflows) using globally distributed data and processing resources.

### SERVICES AVAILABLE

- Service to scientists and data analysts to perform data processing
- Product for use in developing processing facilities requiring highly scalable solutions
- Implementation and customisation
- Implementation and customisation

### ABOUT SPACE APPLICATIONS SERVICES

Space Applications Services NV/SA is an independent Belgian company founded in 1987, with a subsidiary in Houston, USA.

Our aim is to research and develop innovative systems, solutions and products and provide services to the aerospace and security markets and related industries. Our activities cover manned and unmanned spacecraft, launch/re-entry vehicles, control centres, robotics and a wide range of information systems.

# Automated Service Builder

Framework for Globally Distributable processing

All interactions with the ASB platform components are performed through their respective APIs. Repeated use of the import tool allows users to create custom processors for use in workflows. All the processes to be executed by the processor are deployed and registered in the platform with the process metadata being registered in the Knowledge Base. A graphical workflow editor (Figure 2) is used for identifying the processes and specifying the flow of the data between these processes (output to inputs connections).

Data flows that are undefined in a workflow are treated as user provided inputs. Input parameters can be given a default value, be configured as visible but read-only for the users or simply hidden.

A form is dynamically generated and includes all the process inputs present in the workflow not connected to a process output and not configured as hidden (Figure 3).

Systematic (event driven or scheduled) and on-demand processing using the generated parameterisation form are supported.

## Installation

ASB can be installed in Stand-alone mode where all the components as well as the processing chains are deployed and run on a single host. This setup is in particular convenient for developing and testing algorithms on small amounts of data and is particularly attractive to algorithm developers.

In Cloud mode, the process execution environment is a Private or Public Cloud, where resources are scalable.

The available processing resources, in the form of VMs, are automatically detected and used to deploy processes. In this mode, intermediate and final products remain in the cloud, close to where they have been generated.

## Operation Environments

There are two distinct environments: the Controller Node, and a Cloud-based Environment, in which Worker Nodes are deployed (Figure 4).

The Controller Node comprises a number of core components, exposing their functions through remotely callable (SOAP or REST) APIs making it possible to distribute the components on several (physical or virtual) hosts, should it be necessary. Its physical location is of little importance. It can be deployed locally or remotely, in a dedicated server, or in a Cloud.

Worker Nodes are Virtual Machines (VMs) running in Cloud Environments. By default, these VMs run an Agent and have no pre-installed processes. Workflow processes are dynamically deployed and executed.

## Multi-platform support

ASB allows users to develop their application on any platform of their own choice and then decide how to integrate it into ASB. Developers collaborating to develop complex workflows will import their algorithms and share them with their co-developers. While service providers may wish to make the algorithm available as a service and charge to use the service on their own platform. Imported algorithms can be used as a process in a workflow. A process in a workflow can be assigned to any platform for execution for which the user has been assigned access.

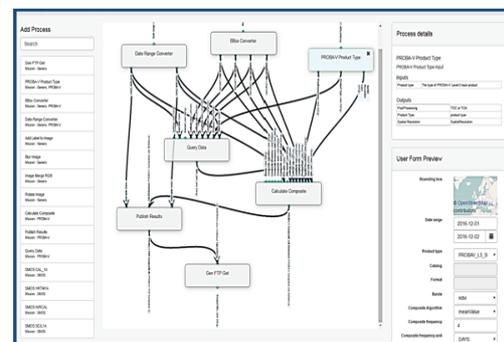

Figure 2 Graphical Workflow Editor

Figure 3 Parameterisation Form

The form shows a map with a bounding box over a region of North America. Below the map, there is a 'Clear Selection' button. The form contains several input fields: 'Date range' with the value '2016-05-01/2016-06-30', 'Product type' with the value 'PROBAV\_L3\_S1\_TOA\_1KM', 'Catalog' with the value 'PROBAV', 'Format' with the value 'HDF5', and 'Bands' with the value 'ndvi'. There are also dropdown menus for 'Product type', 'Catalog', 'Format', and 'Bands'.

## ASB Components

### Product Catalogue

The Product Catalogue stores the metadata of all the products available in the system.

The actual products are persisted in the Cloud. These products are accessible for download to the registered and authenticated end-users. The Product Catalogue gives also the possibility to search for specific products according to criteria.

### Knowledge Base

The Knowledge Base contains the information necessary to generate the products. In particular, it stores the definition of knowledge elements such as data types, input and output parameters, processes and processors.

### Process Import Tool

The Process Import Tool is a Web application which allows importing and preparing user code as dockerized processes. Templates are used to make sure users have a correctly built process that includes the inputs and outputs. Popular Programming languages (Python, R) and libraries (GDAL, SNAP) are installed. Other languages and libraries can be resolved by importing the libraries when the docker is built. The Process Import Tool makes it possible for users to create their own libraries of modules that can be used to build workflows and share with co-developers. The Process Import Tool imposes no restrictions on the programming language.

## Service Builder

The Service Builder transforms product requests into Workflow Execution Orders by fetching the necessary definitions from the Knowledge Base, injecting user-provided inputs if any, and resolving the dependencies between the processes. The Orders are transmitted to the Workflow Engine for execution.

## Workflow Engine

The Workflow Engine is in charge of executing processor workflows. Individual process execution requests are sent to the Task Manager.

## Task Manager

The Task Manager's role is to abstract the execution of each task launched by the Workflow Engine, by hiding the Cloud Environment where the tasks are executed. The Task Manager balances the load of the tasks stemming from the Workflow Engine according to the resources deployed in the Cloud.

## Resource Manager

The component maintains a registry of all the processes that can be deployed.

## Process Images Registry

The Process Images Registry stores the image of the Docker containers in which the processing services are installed. Images are available for download, instantiation and execution. Each of these images may be instantiated and started multiple times within the same VM or within several VMs.

## APPLICATIONS

ASB caters for users with preliminary algorithms to test or algorithms ready to be used to create a systematic highly scalable big data processing service.

ASB is designed for defining, managing and executing complex heterogeneous processing chains (workflows) using globally distributed data and processing resources.

## SERVICES AVAILABLE

- Service to scientists and data analysts to perform data processing
- Product for use in developing processing facilities requiring highly scalable solutions.
- Implementation and customisation
- Implementation and customisation

## BECOME A USER

ASB is offered as a service, implemented by Space Applications Services or as a product to develop a processing facility supported by Space Applications Services.

## Log Manager

The Log Manager collects and stores the log traces issued by the other ASB components. It also gives the administrator the possibility to browse and query these data in a highly configurable Web-based interface.

## End-user Interface

The End-user interface is the web-based graphical front-end that allows an End-user to access the Product Catalogue and request the generation of new Products. This interface also allows following the progress of the products being built and to access information about the products that have been generated in the past.

## Administration Interface

The Administration interface gives access to the various administration interfaces implemented in the ASB Core Components.

## Future Releases

ASB is still being extended and improved in already on-going activities.

This includes additional functionalities for post-editing knowledge base definitions, enhancing the collaboration environment, and providing customisable reports.

Support for using HPC environments as processing platforms is in the works, as well as the development of a generic, customisable and extensible end-user dashboard.
